The compounds [I] of this invention are effective on preventing or relieving diabetic complications.

In diabetic patients, high levels of hexoses (e.g., glucose, galactose. etc.) in blood lead to the accumulation of sugar alcohols (e.g., sorbitol, galactitol, etc.) in tissues. It is known that this accumulation causes the swelling of cells to induce complications of diabetic cataract, diabetic retinopathy, diabetic nephropathy, diabetic neuropathy, etc. [R. Quan-Ma et al., Biochem. Biophys. Res. Comm., 22, 492 (1966)]. For example, R. Gitzelman et al.

have presented that cataract is caused by the accumulation of sugar alcohols [Exptl. Eye. Res., 6, 1 (1967)]. A report of Kinoshita et al. has demonstrated that aldose reductase which reduced aldose to the corresponding sugar alcohols was involved in the initiation of these diabetic complications and that effective inhibitors of aldose reductase were useful [Jpn. J. Ophthalmol., 20, 339 (1976)]. On the basis of the above information, aldose reductase inhibition of the compounds [I] of this invention was tested. The results of the examinations demonstrated that these compounds have potent inhibitory activities on aldose reductase, and therefore they are useful as drugs for therapy or prophylaxis of the diabetic complications.

On the other hand, it has been known that a kind of the derivatives of thiazolidine- or pyrrolidinecarboxylic acid have potent inhibitory activity to angiotensin I-converting enzyme, but thiazolidine and pyrrolidine compounds of this invention are novel compounds, and have more potent inhibitory activities to angiotensin I-converting enzyme. Furthermore, the compounds of this invention are prepared by convenient methods, and are superior to the stability.

Thus, the compounds of this invention are useful as therapeutic or prophylactic agents and antihypertensive agents.

The compound of formula [I] can form the conventional

salts to be generally used as medicine such as sodium salt, potassium salt, calcium salt, magnesium salt, alminum salt, ammonium salt, diethylamine salt, triethanolamine, etc.

The compounds of formula [I] have the stereoisomers which are within the limit of this invention, because they have one or more asymmetric carbon atoms.

Typical examples are shown below, although this invention is not limited to these examples.

PHARMACOLOGICAL TEST 1

It has been known that aldose reductase participates in diabetic cataract which is one of the diabetic complications and that appearance is retarded or depressed by inhibition of the aldose reductase [Acta Societatis Ophthalmologicae Japonicae, 80, 1362 (1976)]. The following method is used for the present test.

(Method)

Aldose reductase is purified from rat lenses according to the method of Hoyman et al. [J. Biol. Chem., 240, 877 (1965)]. Action of the compounds (I) of this invention is evaluated by measurement of optical density according to the J.H. Kinoshita's method [Invest. Ophthal., 13, 713 (1974)]. The reaction mixture for the measurement of the aldose reductase activity is 3.0ml [0.067M phosphate buffer solution (pH 6.2), 0.46M lithium sulfate, 5×10^{-5}M NADPH, 4×10^{-4}M DL-glyceraldehyde, 10U aldose reductase, 10^{-4} to 10^{-10}M the compounds (I)] as total volume, and the absorbance thereof is measured at 340nm.

(Result)

Table VI shows that the compounds (I) of this invention have a strong aldose reductase inhibition effect.

PHARMACOLOGICAL TEST 2

As the method of measurement of angiotensin I-converting enzyme activity, bioassay for the contractile response of isolated smooth muscle or the pressor response of normal animals and biochemical assay for the enzyme isolated from lung or other organs of animals are known. The former is found more advantageous than the latter for the examination of the convertion of angiotensin I to angiotensin II in vivo.

In the present study, therefore, we adopted the bioassay for contractile response of isolated guinea pig ileum to angiotensin I.

(Method)

Isolated guinea pig ileum was suspended in the organ bath containing 20ml of Tyrode's solution of 30°C gassed with 95% O_2 + 5% CO_2. The contraction induced by the addition of angiotensin I (0.1µg/ml) at intervals of 10 minutes was recorded on a recticorder (Nihon Koden) for 90 seconds using FD pick up (ST-1T-H, Nihon Koden)

The test compounds were added to the bath 5 minutes before the addition of angiotensin I.

The inhibitory activity of angiotensin I-converting enzyme was calculated by the following formula.

$$\frac{A - B}{A} \times 100$$

A: contractile intensity of angiotensin I before addition of the compound

B: contractile intensity of angiotensin I after addition of the compound

From the fact that kininase II, which destroys bradykinin having contractive action on isolated guinea pig ileum, is thought to be identical with angiotensin I-converting enzyme augmentation of the contractile response to bradykinin by test compounds was examined

by using bradykinin (0.005μg/ml) in place of angiotensin I according to the above mentioned method.

(Result)

Concentration of a number of the compounds of this invention, which produced 50% inhibition of angiotensin I activity or augmentation of bradykinin activity inducing the contraction of guinea pig ileum, fell in the range of 10^{-7} ~ 10^{-9}M.

PHARMACOLOGICAL TEST 3

The activity of angiotensin I-converting enzyme was measured by spectrophotometry according to the method of D.W. Cushman and H.S. Cheung [Biochem. Pharmacol., 20, 1637 (1971)]. That is, the absorbance of hippuric acid was measured, which is liberated by incubating hippuryl-L-histidyl-L-leucine (HHL) as substrate in the presence of angiotensin I-converting enzyme extracted from rabbit lung.

(Method)

The reaction mixture is as follows:

100mM phosphate buffer (pH 8.3)

300mM sodium chloride

5mM HHL

10^{-3} ~ 10^{-9}M enzyme inhibitor

5mU enzyme

0.25ml of the above mixture was incubated at 37°C for 30 minutes and the reaction was stopped by adding 0.25ml of 1 N hydrochloric acid. To this solution, 1.5ml of ethyl acetate was added in order to extract hippuric acid. 1.0ml of ethyl acetate layer was collected and evaporated to dryness, and the residue obtained was dissolved in 1.0ml of water. The absorbance of this solution was measured at 228nm.

The inhibitory activity of angiotensin I-converting enzyme was calculated by the following formula:

$$\text{Percent inhibition} = \frac{A - B}{A} \times 100$$

A: absorbance of reaction solution before addition of the compound

B: absorbance of reaction solution after addition of the compound

Concentration of compound producing 50% inhibition of angiotensin I-converting enzyme (IC_{50}).

The solution containing compounds at the concentration of 1×10^{-3}M to 1×10^{-9}M was incubated and percent inhibition at each concentration was calculated according to the above formula, and then IC_{50}, concentration of the compound producing 50% inhibition of the enzyme activity, was determined.

(Result)

IC_{50} of a number of the compounds of this invention,

fell in the range of 10^{-7} - 10^{-10}M.

TOXICITY TEST

The acute toxicity of compounds 47 and 56 is 1000 - 1500mg/kg.

(Experimental animals)

The male ddy-std. strain mice (4 weeks of age, weighing 19-21g) were placed in a breeding room of constant temperature and humidity (23±1°C, 55±5%) and fed freely pellet diet (CE-2, Clea Japan, Inc.) and water ad. libitum for a week. The mice showing the normal growth were selected for the experiment.

(Method of administration)

Test compounds are dissolved in distilled water and administered (i.v.) in a dose of 0.5ml/20g body weight.

It is found in the above pharmacological and toxicity test that the compounds (I) of this invention are useful as drugs for therapy or prophylaxis of the diabetic complications and as antihypertensive agents.

In case the compounds are used for preventing or relieving diabetic complications, the dosage forms are tablet, capsule, granule, powder, suppository, injection, ophthalmic solution, ophthalmic ointment, etc. These preparations can also contain general excipients.

On the other hand, in case the compounds are used for reducing blood pressure, they can be given with the combination of diuretics such as probenecid, carinamide, hydroflumethiazide, furosemide, and bumetanide same as other antihypertensive agents. The compounds can be administered either orally or parenterally. The dosage forms are tablet, capsule, granule, powder, suppository, injection, etc. In the treatment of hypertension, these preparations can contain not only general excipients but also other antihypertensive agents such as reserpine, α-methyldopa, guanethidine, clonidine, hydralazine, etc., or β-adrenergic blocking agents such as propranolol, alprenolol, pindolol, bufetolol, bupranolol, bunitrolol, practolol, oxprenolol, indenolol, timolol, bunolol, etc.

The dose is adjusted depending on symptom, dosage form, etc. But, usual daily dosage is 1 to 5000mg, preferably 10 to 1000mg, in one or a few divided doses.
